

CELL CYCLE & DIVISION

CELL CYCLE

Sequence of events through which cell duplicates its genome, synthesizes other cell constituents and divides into two daughter = Cell growth + DNA replication + Cell division.

Time taken : Yeast = 90 min, Human = 24hrs.

ANIMALS

Only diploid cell divide by mitosis
(except male honey bees)

PLANTS

Both haploid & diploid cells
show mitotic division

M-PHASE

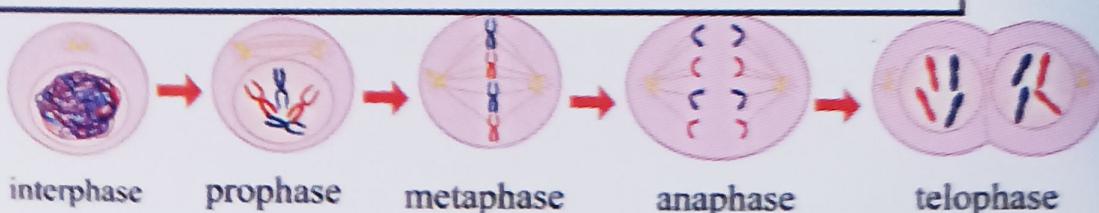

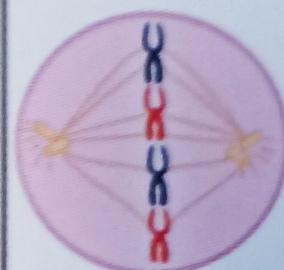

- Reorganisation of cell components
- Equational division
- Includes Karyokinesis & Cytokinesis.

Prophase (Divisions of Karyokinesis)

- Chromosomal material start condensing (untangles)
- Chromatin condensation
- Centrosome moves towards opposite poles (radiates out microtubules - asters)
- Mitotic Apparatus= 2 asters + Spindle fibres
- **End of prophase** - Golgi complex (-), endoplasmic reticulum (-), nucleolus(-), nuclear envelope(-)

Metaphase

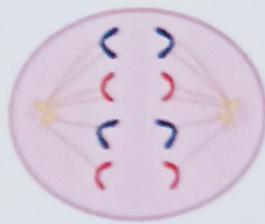

- Nuclear envelop completely disintegrates
- Condensation of chromosomes complete
- Spindle fibers attach to kinetochores.
- Chromosomes align to the cell center (equator), spindle fibers connected to poles. Metaphase plate.

15

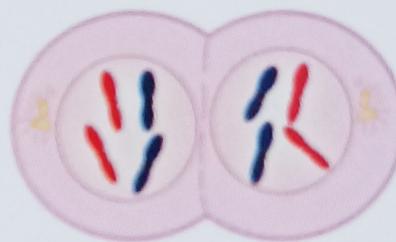

Anaphase

- Chromosomes split → daughter chromatids
- Chromatids moves towards opposite poles
- Centromere directed towards pole, chromosome trailing behind

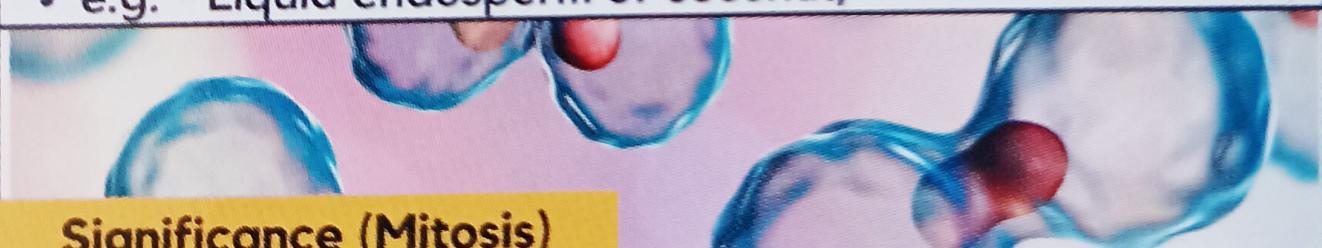

Telophase

- Chromosome decondense at poles (loose identity as discrete elements)
- Nuclear envelope & daughter nuclei form.
- Nucleolus, Golgi body, ER reforms

Cytokinesis

- Furrow in plasma membrane extends → joins (Animal cells)
- Plant cells-
cell wall grows outward & meets lateral walls (precursor-cell plate) → represents middle lamella
- Sometime cytokinesis does not occur forms → syncytium
- e.g. - Liquid endosperm of coconut,

Significance (Mitosis)

1. Produces daughter cells with identical genetic makeup
2. Helps in growth in multicellular organisms
3. Only mode of multiplication in unicellular organisms
4. Restores nucleo-cytoplasmic ratio.
5. Important in cell repair & replacement.
