iii. Cr^{3+} is a stronger reducing agent than Fe^{2+} .

19. **Answer the following:**

- (a) The time required to decompose SO_2Cl_2 to half of its initial amount is 60 min. If the decomposition [1] is a first order reaction, calculate the rate constant of the reaction?
- (b) The decomposition reaction of ammonia gas on platinum surface has a rate constant $k = 2.5 \times 10^{-4}$ [1] mol L⁻¹ s⁻¹. What is the order of the reaction?
- 20. What is expected Van't Hoff factor for $K_{4[}Fe(CN)_{6}]$?

22. The K_{sp} for AgCl at 298 K is 1.0×10^{-10} . Calculate the electrode potential for Ag⁺/Ag electrode immersed in [3] 1.0M KCl solution. Given $\mathbf{E}^{\theta}_{\mathbf{Ag}^+/\mathbf{Ag}} = 0.80V$.

For the reaction: [3]
$$2A + B \rightarrow A_2B$$

the rate = $k[A][B]^2$ with $k = 2.0 \times 10^{-6} \text{ mol}^{-2} \text{ L}^2 \text{ s}^{-1}$. Calculate the initial rate of the reaction when $[A] = 0.1 \text{ mol} \text{ L}^{-1}$, $[B] = 0.2 \text{ mol} \text{ L}^{-1}$. Calculate the rate of reaction after [A] is reduced to 0.06 mol L^{-1} .

24. Give the structure of the products you would except when each of the following alcohol reacts with (i) Butan-l- [3] ol (ii) 2- Methylbutan-2-ol

a. HCl - ZnCl₂

b. HBr

Name the reagents which are used in the following conversions:

i. A primary alcohol to an aldehyde

- ii. Butan-2-one to butan-2-ol
- iii. Phenol to 2, 4, 6-tribromophenol

25. Describe the following:

i. Acetylation

ii. Cannizzaro reaction

- iii. Cross aldol condensation
- iv. Decarboxylation

26. In the button cell widely used in watches and other devices the following reaction takes place:

 $Zn(s)+Ag_2O(s)+H_2O(l)
ightarrow Zn^{2+}(aq)+2Ag(s)+2OH^-(aq)$

Determine $\Delta_r G^{(-)}$ and $\mathrm{E}^{(-)}$ for the reaction

29. **Read the following text carefully and answer the questions that follow:**

KMnO₄ and K₂Cr₂O₇ are most important chemicals which are used as oxidising agents and disinfectants. K₂MnO₄ is prepared by fusing MnO₂ with KOH in presence of O₂. K2MnO₄ is electrolysed to get purple coloured KMnO₄. Na₂CrO₄ is prepared by heating chromite ore with Na₂CO₃ in presence of O₂. Na₂CrO₄ is converted into Na₂Cr₂O₇ by reacting with concentrated H₂SO₄. Na₂Cr₂O₇ is reacted with KCl to get K₂Cr₂O₇, orange coloured solid, soluble in water, changes to yellow coloured CrO_4^{2-} in basic medium, KMnO₄ acts as oxidising agent in acidic, neutral as well basic medium. In acidic medium, it converts Fe²⁺ to Fe³⁺, Sn²⁺ to Sn⁴⁺, COO⁻ to CO². In basic medium it converts I⁻ to IO³⁻. K₂Cr₂O₇ acts as oxidising agent only in acidic medium, converts H₂S to S, SO₂ to SO4²⁻, I⁻ to I₂. Lanthanoids and actinoids belong to f-block elements with general electronic configuration (n - 2) f^{1 to 14} (n - 1) d^{0 - 2} ns². All actinoids are radioactive. Both show contraction in atomic and ionic radii but actinoid contraction is more than lanthanoid contraction. Lanthanoid show +3 oxidation state, few elements show +2 and +4 oxidation states also. Actinoids show +3, +4, +5, +6, +7 oxidation states.

30. Read the following text carefully and answer the questions that follow:

Raoult's law for volatile liquids states that the partial vapour pressure of each component in the solution is directly proportional to its mole fraction, whereas for a non-volatile solute, it states that the vapour pressure of a solution of a non-volatile solute is equal to the vapour pressure of the pure solvent at that temperature multiplied by its mole fraction. Two liquids A and B are mixed with each other to form a solution, the vapour phase consists of both components of the solution. Once the components in the solution have reached equilibrium, the total vapour pressure of the solution can be determined by combining Raoult's law with Dalton's law of partial pressures. If a non-volatile solute B is dissolved into a solvent A to form a solution, the vapour pressure of the solution will be lower than that of the pure solvent. The solutions which obey Raoult's law over the entire range of concentration are ideal solutions, whereas the solutions for which vapour pressure is either higher or lower

than that predicted by Raoult's law are called non-ideal solutions. Non-ideal solutions are identified by determining the strength of the intermolecular forces between the different molecules in that particular solution. They can either show positive or negative deviation from Raoult's law depending on whether the A - B interactions in solution are stronger or weaker than A - A and B - B interactions.

Solution

Section A

1. **(a)** C₂H₅-I

Explanation: For the same alkyl group the boiling points of haloalkanes are in the order of RF < RCl < RBr < RI as with the increase in size of halogen atom the magnitude of van der Waals forces of attraction increases, resulting in higher boiling points.

2. (a) H₂N.CH₂.COOH

Explanation: Amino acids contain amino (-NH₂) and carboxyl (-COOH) functional groups.

3.

(c) i, ii, iii

- Explanation:
 - Preparation of phenols from haloarenes: Chlorobenzene is an example of haloarenes which is formed by monosubstitution of the benzene ring. When chlorobenzene is fused with sodium hydroxide at 623K and 320 atm sodium phenoxide is produced. Finally, sodium phenoxide on acidification gives phenols.
 - Preparation of phenols from diazonium salts: When an aromatic primary amine is treated with nitrous (NaNO₂ + HCl) acid at 273 278 K, diazonium salts are obtained. These diazonium salts are highly reactive in nature. Upon warming with water, these diazonium salts finally hydrolyse to phenols. Phenols can also be obtained from diazonium salts by treating it with dilute acids.
 - **Preparation of phenols from benzene sulphonic acid**: Benzenesulphonic acid can be obtained from benzene by reacting it with oleum. Benzenesulphonic acid thus formed is treated with molten sodium hydroxide at high temperature which leads to the formation of sodium phenoxide. Finally, sodium phenoxide on acidification gives phenols.

4.

(b) (CH₃)₂C(OC₂H₅)(OC₂H₅)

Explanation: Ketones or aldehydes react with alcohols to form acetals. This reaction of alcohol on aldehydes or ketones is catalyzed in the presence of acid and is a reversible reaction. Firstly a hemiacetal $(CH_3)_2C(OH)(OC_2H_5)$ is formed which further reacts with alcohol to give acetal.

 $(CH_3)_2C(OC_2H_5)(OC_2H_5) CH_3COCH_3 + 2C_2H_5OH \stackrel{H^+}{\rightleftharpoons} (CH_3)_2C(OC_2H_5)(OC_2H_5)$

(c) quadruple

Explanation: The rate of the reaction is quadruple.

6.

5.

(b) Etard reactionExplanation: Etard reaction

11.

(d) 3-methylphenol **Explanation:**

-OH is a functional group and -CH₃ is the substituent. We start numbering from the side of the main functional group -OH.

IUPAC name: 3-methyl phenol

12.

(d) Benzene sulphonyl chloride

Explanation: Benzene sulphonyl chloride, $C_6H_5SO_2Cl_2$, is called Hinsberg reagent. It is used to distinguish between primary, secondary and tertiary amines.

13.

(c) A is true but R is false.Explanation: A is true but R is false.

14.

(b) Both A and R are true but R is not the correct explanation of A.Explanation: Both A and R are true but R is not the correct explanation of A.

15. **(a)** Both A and R are true and R is the correct explanation of A.

Explanation: (CH₃)₃-C-O-CH₃ is an ether with two different alkyl groups, of which (CH₃)₃-C-I, tertiary alkyl group, on

reaction with hydrogen halide (HI) forms a tertiary halide.

This occurs as the reaction is an S_N1 reaction. The reaction involves the formation of a stable carbocation. If the ether has a primary alkyl group, then the reaction follows the S_N2 mechanism.

(a) Both A and R are true and R is the correct explanation of A.
 Explanation: Williamson's synthesis is not applicable to tert. alkyl halides because alkoxide ions being both powerful nucleophiles and bases would bring dehydro-halogenation of the tert. alkyl halides to form alkenes preferentially.

ii. Mn²⁺ has d⁵ configuration (stable half-filled configuration)

iii. d^5 to d^3 occurs in case of Cr^{2+} to Cr^{3+} . (More stable t^3_{2q}) while it changes from d^6 to d^5 in case of Fe^{2+} to Fe^{3+} .

It now undergoes dsp² hybridization. Since all electrons are paired, it is diamagnetic. In case of [NiCl₄]²⁻, CN⁻ ion is a weak field ligand. Therefore, it does not lead to the pairing of unpaired 3d electrons. Therefore, it undergoes sp³ hybridization.

Since there are 2 unpaired electrons in this case, it is paramagnetic in nature.
