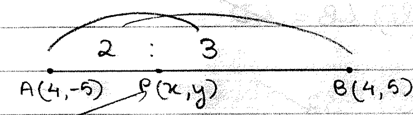
21. A(4, −5) and B(4, 5)

(a) Let the coordinates of point P which divides AB such that AP : AB = 2 : 5 be P(x, y).



$$\frac{AP}{AB} = \frac{2}{5}$$

$$\Rightarrow \frac{AP + PB}{AP} = \frac{5}{2}$$

$\Rightarrow 2PB = 3AP \Rightarrow AP : PB = 2 : 3$

P divides AB internally in the ratio of 2 : 3

By section formula,

$$P(x, y) = P\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}\right)$$

$$\Rightarrow P(x, y) = P\left(\frac{2 \times 4 + 3 \times 4}{2+3}, \frac{2 \times 5 + 3 \times (-5)}{2+3}\right)$$

$$\Rightarrow P(x, y) = P\left(\frac{20}{5}, \frac{-5}{5}\right) = P(4, -1)$$

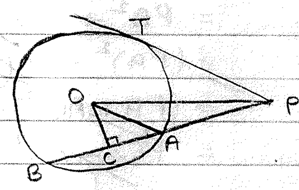
$\therefore$ Coordinates of P are $\boxed{P(4, -1)}$

22. Given : Circle with centre O

PT is a tangent

$OC \perp AB$

To Prove : $PA \cdot PB = PC^2 - AC^2$



Proof: Perpendicular from centre to chord bisects it

$\Rightarrow$ C is midpoint of AB $\quad$ ($\because \angle OCA = 90°$, given)

$\Rightarrow BC = CA = \dfrac{AB}{2}$

$\Rightarrow AB = 2AC$

By Pythagoras Theorem,

In right ΔOCA, $OA^2 = OC^2 + AC^2$

In right ΔOCP, $OP^2 = OC^2 + PC^2$

$$
\begin{aligned}
LHS &= PA \cdot PB \\
&= PA \times (PA + AB) \\
&= PA^2 + PA \cdot AB \\
&= PA^2 + PA \cdot 2AC \quad \text{(from ①)} \\
&= (PA)^2 + 2(PA)(AC) \\
&= (PA + AC)^2 - AC^2 \quad [(a+b)^2 = a^2 + 2ab + b^2] \\
&= PC^2 - AC^2 = RHS

LCM $(96, 120) = 2^5 \times 3 \times 5$

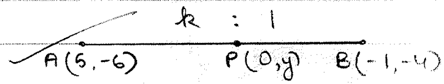
24\. Points are $A(5,-6)$ and $B(-1,-4)$

Let the point where y-axis $(x=0)$ intersects AB be $P(0,y)$



Let the ratio in which $P(0,y)$ divides AB be $k:1$

By section formula,

$$P(x,y) = \left(\frac{mx_2+nx_1}{m+n}, \frac{my_2+ny_1}{m+n}\right)$$

$$\Rightarrow P(0,y) = \left(\frac{-k+5}{k+1}, \frac{-4k+(-6)}{k+1}\right)$$

$$\Rightarrow 0 = \frac{-k+5}{k+1} \quad \text{and} \quad y = \frac{-4k-6}{k+1}$$

$$\Rightarrow 0 = -k+5$$

$$\Rightarrow k = 5$$

$$\Rightarrow k:1 = 5:1$$

$\therefore$ Ratio is $\boxed{5:1}$

25 (a) $a\cos\theta + b\sin\theta = m$

$a\sin\theta \cancel{+} - b\cos\theta = n$

To prove: $a^2 + b^2 = m^2 + n^2$

$a\cos\theta + b\sin\theta = m$

Squaring both sides,

$a^2\cos^2\theta + b^2\sin^2\theta + 2ab\sin\theta\cos\theta = m^2$ $\left[\begin{matrix}(a+b)^2 \\ = a^2 + b^2 + 2ab\end{matrix}\right]$

$a\sin\theta - b\cos\theta = n$

Squaring both sides,

$a^2\sin^2\theta + b^2\cos^2\theta - 2ab\sin\theta\cos\theta = n^2$ $\left[\begin{matrix}(a-b)^2 \\ = a^2 + b^2 - 2ab\end{matrix}\right]$

Adding 1 and 2,

$(a^2\cos^2\theta + a^2\sin^2\theta) + (b^2\sin^2\theta + b^2\cos^2\theta) + 2ab\cancel{\sin\theta\cos\theta}$
$-2ab\cancel{\sin\theta\cos\theta} = m^2 + n^2$

$\Rightarrow a^2(\sin^2\theta + \cos^2\theta) + b^2(\sin^2\theta + \cos^2\theta) = m^2 + n^2$

$\because \sin^2\theta + \cos^2\theta = 1$

$\Rightarrow a^2 + b^2 = m^2 + n^2$

LHS = RHS

26. (a.) Let us assume, to the contrary, that $\sqrt{3}$ is rational.

$\Rightarrow \sqrt{3} = \frac{p}{q}$ where $q \neq 0$, p and q are coprime positive integers

Squaring both sides,

$\Rightarrow 3 = \frac{p^2}{q^2}$

$\Rightarrow p^2 = 3q^2$

$\Rightarrow$ 3 divides p^2

$\Rightarrow$ 3 divides p ($\because$ 3 is prime)

So, let $p = 3m$

Substituting in ,

$(3m)^2 = 3q^2$

$\Rightarrow 9m^2 = 3q^2$

$\Rightarrow q^2 = 3m^2$

$\Rightarrow$ 3 divides q^2

$\Rightarrow$ 3 divides q

From ③ and ④,
3 divides ~~both~~ p and q
But p and q are coprime, i.e. HCF$(p, q) = 1$ (Using ①)
which is a contradiction
∴ our supposition is wrong
∴ $\sqrt{3}$ must be irrational.
Hence, proved

27 Let the first term of AP be a
and common difference be d
AP : $a, a+d, a+2d, \ldots$
$a_n = a + (n-1)d$

$a_p = a + (p-1)d = q$
$\Rightarrow a + pd - d = q$
$a_q = a + (q-1)d = p$
$\Rightarrow a + qd - d = p$

Subtracting ① from ②,

$$\cancel{a} + qd - \cancel{d} = p$$
$$\cancel{a} + pd - \cancel{d} = q$$
$$\ominus$$
$$(q-p)d = p-q$$
$$\Rightarrow d = -1$$

Substituting in ①,

$$a + p(-1) - (-1) = q$$
$$\Rightarrow a + 1 = p + q$$

$$a_n = a + (n-1)d$$
$$= a + (n-1)(-1)$$
$$= a - n + 1$$
$$= (a+1) - n$$
$$= p + q - n \quad \text{(Substituting from ③)}$$

LHS = RHS

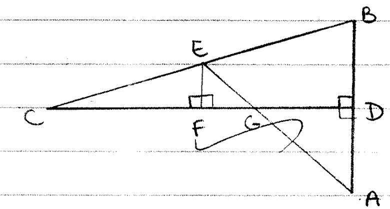
Hence, proved

28 (a) **Given**: CD is $\perp$ bisector of AB

$EF \perp CD$

AE intersects CD at G

To Prove: $\dfrac{CF}{CD} = \dfrac{FG}{DG}$



Proof: In $\triangle EFG$ and and $\triangle ADG$,

$\angle EFG = \angle ADG = 90^\circ$ (given, linear pair with $\angle EFC$ and $\angle BDG$)

$\angle EGF = \angle AGD$ (vertically opposite angles)

$\therefore \triangle EFG \sim \triangle ADG$ (by AA similarity criterion)

$\Rightarrow \dfrac{EF}{AD} = \dfrac{FG}{DG}$ (~~cpst~~)

In $\triangle ECF$ and $\triangle BCD$,

$\angle EFC = \angle BDC = 90^\circ$ (given)

$\angle ECF = \angle BCD$ (common angle)

$\therefore \triangle ECF \sim \triangle BCD$ (by AA similarity criterion)

$\Rightarrow \dfrac{EF}{BD} = \dfrac{CF}{CD}$ (~~cpst~~)

But $AD = BD$ $\quad (\because CD$ bisects $AB)$

$$\Rightarrow \frac{EF}{AD} = \frac{EF}{BD} = \frac{CF}{CD} \quad (2)$$

From ① and ②,

$$\frac{EF}{AD} = \frac{CF}{CD} = \frac{\cancel{FD}\ FG}{DG}$$

$$\therefore \cancel{FG}\ \frac{CF}{CD} = \frac{FG}{DG}$$

Hence, ~~proved~~

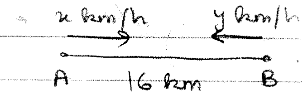
29. Let the speed of person 1 be x ~~km~~/h
and speed of person 2 be y ~~km~~/h $\quad (x > y)$

distance = speed × time
Given distance = 16 km

Case 1 : Towards each other



Time = 2 h

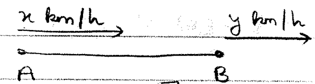
Speed = $(x+y)$ km/h

Distance = $2(x+y)$ km

$\Rightarrow \quad 16 = 2x + 2y$

$\Rightarrow \quad x + y = 8$

Case 2 : Same direction



Time = 8 h

Speed = $(x-y)$ km/h

Distance (only AB) = $8(x-y)$ $\quad [16 + 8y = 8x]$

$\Rightarrow \quad 16 = 8x - 8y$

$\Rightarrow \quad x - y = 2$

Adding (1) and (2),

$$\begin{aligned} x + \cancel{y} &= 8 \\ \oplus \; x - \cancel{y} &= 2 \\ \hline 2x &= 10 \\ \Rightarrow x &= 5 \end{aligned}$$

Substituting in 1,

$y = 3 \cancel{km}$

$\therefore$ Speed of person 1 = $\boxed{5 \text{ km/h}}$

Speed of person 2 = $\boxed{3 \text{ km/h}}$
