

10. Study of Animal Tissues

- Tissues are the group of cells that work together to perform a particular function
- Cells give rise to tissues and an organ system is formed by many tissues. When inter related organs work in a coordinated manner, they form an organ system. Many organ systems are present in the body of an organism
- Species, populations, communities, ecosystem, biome and finally biosphere are the higher levels of organization.
- The various higher and lower levels of organization can be summarized as follows.

Animal tissues: Animal tissues are classified into four types based on the functions they perform: Epithelial, Connective, Muscular and Nervous tissue.

- **Epithelial tissues** –Tightly packed cells with almost no intercellular spaces. It forms the covering of the external surfaces, internal cavities, and organs of the animal body
- Various types of epithelial tissues:
- **Squamous epithelium** - Single layer of extremely thin and flat cells are called simple squamous epithelium while multi layered cells forms stratified squamous epithelium in order to prevent wear and tear
- **Location in the human body:**
 - Simple squamous epithelium - Lining of the mouth, oesophagus, lung alveoli, etc.
 - Stratified squamous epithelium – Skin
- **Cuboidal epithelium** - Consists of cube-like cells that provide mechanical support
 - **Location in the human body:**Lining of kidney tubules and ducts of the salivary glands
- **Columnar epithelium** - Consists of elongated or column-like cells to facilitate movement across the epithelial barriers.
 - **Location in the human body:** Inner lining of the intestine and gut

- **Glandular epithelium** - Consists of multicellular glands

Connective tissues -Specialised to connect various body organs. Various types of connective tissues are:

Loose connective tissue- It includes areolar and adipose connective tissues

- **Areolar tissue** - It provides supports to internal organs and helps in repair of tissues
 - Found in the skin and muscles, around the blood vessels, nerves, etc.
- **Adipose tissue** - Acts as the storage site of fats; found between the internal organs and below the skin; acts as an insulator for the body

Dense regular connective tissue- Main components are tendons and ligaments.

- Ligaments – Connective tissues that connect a bone to a bone. It is very elastic
- Tendons – Connective tissue that connect a bone to a muscle. It has limited flexibility

Specialized connective tissue -It includes skeletal tissues i.e cartilage and bone.

Fluid connective tissue - Blood is the special connective tissue present in animals that helps in the transport of various substances. It is composed of plasma, Red blood cells (RBC), White blood cell (WBC) and platelets.

Lymph- It is a transparent, light yellowish fluid located in the intercellular spaces of our body. It is part of the defensive mechanism of the body and also helps in transporting nutrients to tissues and cells. It also helps in carrying digested fats from the intestine.

Muscular Tissues

Muscles, made up of muscular tissues, make it possible for the different body parts to move.

Muscular tissues can be classified into three categories, as is shown in the figure.

Striated Muscles

- Striated muscles show alternate light and dark bands or striations when stained appropriately.
- They are also called **skeletal muscles** because they are found attached to the bones which form the skeleton.
- They are voluntary muscles.
- The cells of striated muscular tissues are long, cylindrical, unbranched and multinucleate (i.e., having many nuclei).
- They are located in the body wall, tongue, limbs and pharynx.

Smooth Muscles

- Unstriated or smooth muscles do not show any alternate light and dark bands.
- They are involuntary muscles as they are involved in involuntary actions of the body.
- The cells of smooth muscular tissues are long with pointed ends (or spindle-shaped) and uninucleate.
- Smooth muscles are located in the alimentary canal, urinary bladder, blood vessels and ducts of glands.

Cardiac Muscles

- Cardiac muscles are the muscles of the heart.
- They are striated, but involuntary in action.
- They show rhythmic contraction and relaxation throughout life.
- The cells of cardiac muscular tissues are cylindrical, branched and uninucleate.
- Cardiac muscles are exclusively present in the heart. They control the rhythmic beating of the heart.

- Nervous tissues –Highly specialised tissues present in the brain, spinal cord, and nerves.
 - Neuron – It is the functional unit of nervous tissue
 - A neuron consists of a cell body, an axon, and a dendrite.
- Cells of the nervous tissues are highly specialized for becoming stimulated and then transmitting the stimulus very rapidly from one place to another within the body.
- Neurons are responsible for both collecting and delivering messages in our body.

Neurons

The fundamental unit of the nervous system is the nerve cell.

Parts of neurons:

- **Dendrite:** It receives information from the axon of an adjacent neuron and conducts it toward the cell body.
- **Axon:** It conducts messages away from the cell body.
- **Cell body:** It contains a nucleus, mitochondria and other organelles. It is concerned with the maintenance and growth of the cell.

Fat containing Schwann cells help in insulating the neurons making them capable of transmitting signals very fast.

The myelin sheath is not continuous over the axon and has some gaps exposing the axon. A gap between two adjacent myelin sheaths is called node of Ranvier.

Transfer of a Nerve Impulse from one to another nerve cell

The axon endings of one nerve cell are loosely placed on the cell body or cyton of another nerve cell, thereby forming a loose connection called synapse. Electric signals are transmitted from one neuron to the next across such synapses through the release of chemicals called neurotransmitters.

A released neurotransmitter crosses a synapse and starts a similar electrical impulse in the dendrite of the adjacent neuron. In this way, impulses are transmitted from one neuron to another and, ultimately, to the brain.

Glial Cells- nervous tissue also contains supportive cells of various kinds which do not help in conduction. These cells are called glial or neuroglial cells

Nerves:

They are formed of a bundle of axons that are enclosed in a sheath.

They are of three types: sensory, motor and mixed.
