11. Reflection of Light

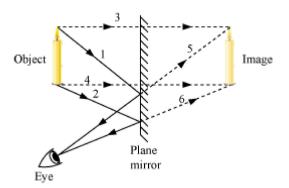

- Light travels only in a straight line in all directions.
- This phenomenon is called the rectilinear propagation of light.
- Light emanating from a source (bulb) travels in all directions.
- The formation of image in a pinhole camera is a proof of rectilinear propagation of light.

•	Medium	Speed of light (in m/s)
	Air/ Vacuum	3×10 ⁸
	Water	2.25×10 ⁸
	Glass	2×10 ⁸

• Reflection of light makes things visible.

- (a) i (Angle of incidence) = r (Angle of reflection)
- (b) AO, OP, and OB lie on the same plane.
 - Laws of reflection:
 - The angle of incident is equal to the angle of reflection
 - The incident ray, the normal at the point of incidence and the reflected ray all lie in the same plane.
 - Image formation by a plane mirror

Left part of the candle appears on the right and its right part appears on the left. This is known as **lateral** inversion.

- Characteristics of images formed by plane mirror
 - virtual and erect
 - same size as of object
 - laterally inverted

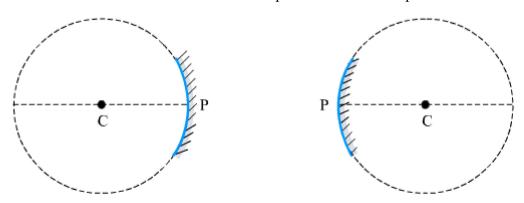

- image distance and object distance are same and perpendicular from mirror
- Virtual images are those images which cannot be obtained on screen. But there are some images which can be obtained on screen. Such images are called real image.

• Uses of plane mirror

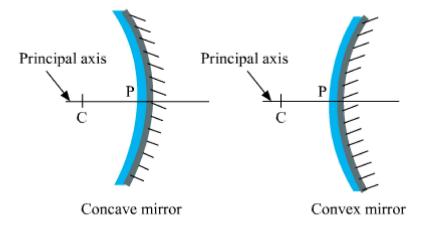

- It is used as a looking glass.
- It is used to increase the effective length of an optician's room.
- In periscope, two parallel plane mirrors are inclined at 45 degrees with vertical walls such that they are facing each other.
- In kaleidoscope, three plane mirrors are inclined with each other at 60 degrees.
- It is used in solar heaters and cookers to heat substances by reflecting the sunlight towards the substances.
- Kaleidoscope works on the principle of multiple reflections.
- **Periscope** is an optical device used to see objects that are not along the line of sight.
- Sunlight consists of several colours.
- Splitting of white light into diffrent colours is called dispersion.
- Number of image formed in multiple reflection = angle between two plane mirros 1

Spherical Mirror

• Centre of curvature: Centre of the sphere of which the spherical mirror is a part

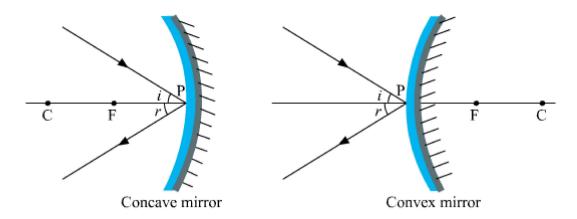

• Pole: It is the midpoint of the aperture of the spherical mirror or mirror centre.

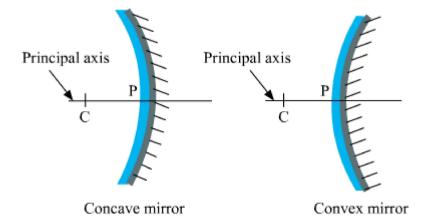

• Focus: Where parallel rays (parallel to the principal axis) meet or appear to meet after reflection.

- Principal Axis: The imaginary line that runs through the pole and the center of curvature of a spherical mirror.
- Distance of focus from the pole is half the radius of curvature.

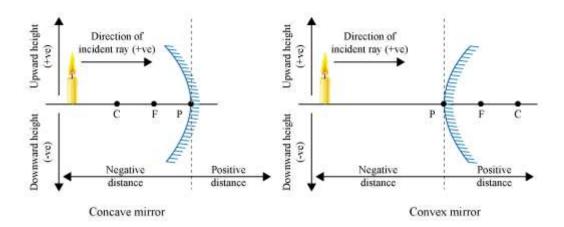

Two types of spherical mirrors

- 1. The image formed by a convex mirror is **erect** and **diminished**. It is formed behind the mirror.
- 2. The image formed by a concave mirror can be **erect as well as inverted**, **diminished as well as magnified**, behind the mirror as well as in front of the mirror, depending on the distance of the object from the mirror.
- 3. The image that can be obtained on a screen is called **real** image. The image that cannot be obtained on a screen is called **virtual** image.
- 4. The image formed by a **convex** mirror is always **virtual**. The image formed by a **concave** mirror can be **real** as well as **virtual**.
- Sign Conventions for Spherical Mirrors:

• Mirror formula

$$\frac{1}{f} = \frac{1}{v} + \frac{1}{u}$$

For concave mirror, f = -ve and for convex mirror, f = +ve

• Magnification

Magnification = -vu

For real image, $v = -v\epsilon$

Virtual image, v = +ve

- 1. Concave mirror is used as the reflector of a torch, dentist mirror, etc. It is also used in solar furnaces.
- 2. Convex mirror is used as a rear view mirror in vehicles. It also used road safety mirrors.
